Bounded Preprocessing Space

Conclusion 00

Basic Idea

Worst-Case Optimal Search-Time

- indexing a text t of size n,
- querying a pattern p of size m,
- allowing a constant number of k errors (Edit distance),
- achieving worst-case optimal query-time O(m + occ) and size O(n log^k n) on average and w.h.p.

RMQ = Cartesian Tree (in O(n))

RMQ = Cartesian Tree(in <math>O(n)) + constant time LCA (in O(n))

RMQ = Cartesian Tree(in <math>O(n)) + constant time LCA (in O(n))

 \Rightarrow Query time is O(1)

Bounded value range queries are solved through successive RMQs, e.g., querying (2,7,6):

The querytree is binary and has |L| inner nodes, hence we need O(|L|) RMQs in total.

Bounded value range queries are solved through successive RMQs, e.g., querying (2,7,6):

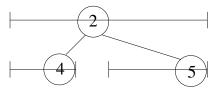

The querytree is binary and has |L| inner nodes, hence we need O(|L|) RMQs in total.

CRQ

Colored range queries are reduced by using another array which stores the last index of each value. A CRQ (i, j) then transforms into a BVRQ (i, j, i - 1) on the new array:

(ロ) (部) (E) (E) (E) (の)

CRQ

Colored range queries are reduced by using another array which stores the last index of each value. A CRQ (i, j) then transforms into a BVRQ (i, j, i - 1) on the new array:

Analysis				

- Set $h_i = maxpref(W_i)$ (the height of $et_i(S)$)
- The error sets have size $|W_i| = O(h_0 h_1 \cdots h_{i-1} |S|)$
- Construction time for $et_i(S)$ is $O(h_0h_1\cdots h_i|S|)$
- $h_i = O(\log n)$ in expectation and with high probability

Weak Tries	and Error Trees			

Weak Tries

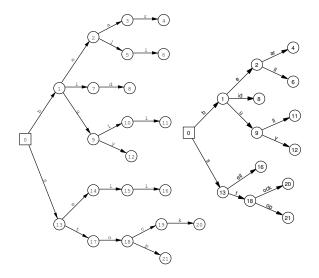

Definition (Weak Trie)

For l > 0, the *l*-weak trie for a set of strings $S \subset \Sigma^*$ is a rooted tree with edges labeled by characters from Σ . For any node with a depth less than l, all outgoing edges are labeled by different characters, and there are no branching nodes with a depth of more than l. Each path from the root to a leaf can be read as a string from S.

Analysis				

Data structure:

- Set $h_i = ck \log n + i$.
- The size is $O(n \log^k n)$.
- The preprocessing takes $O(n \log^{k+1} n)$ (weak tries!).

Searching:

- For $m \leq ck \log n$: as before in $O(m + \operatorname{occ})$ time.
- For $m > ck \log n$: use a generalized suffix tree (as a filter).

Conclusion

Conclusion and Open Problems

Open Problems

• Can we close the gap?

- Our new indexing structure works best for "small" patterns of length $O(\log n)$.
- On average, "small" patterns are the hardest to find.
- The case of "large" patterns of length $\Omega(\log^k n)$ can be handled with the data structure of Cole et. al 2004.
- No lower bounds on the index size for O(m + occ)-time lookup are known.

• Can we use it?

Open Problems

- Can we close the gap?
 - Our new indexing structure works best for "small" patterns of length $O(\log n)$.
 - On average, "small" patterns are the hardest to find.
 - The case of "large" patterns of length $\Omega(\log^k n)$ can be handled with the data structure of Cole et. al 2004.
 - No lower bounds on the index size for O(m + occ)-time lookup are known.

• Can we use it?

Conclusion	and Open Problems			

- Can we close the gap?
 - Our new indexing structure works best for "small" patterns of length $O(\log n)$.
 - On average, "small" patterns are the hardest to find.
 - The case of "large" patterns of length $\Omega(\log^k n)$ can be handled with the data structure of Cole et. al 2004.
 - No lower bounds on the index size for O(m + occ)-time lookup are known.
- Can we use it?
 - Constant factors are largel
 - Implementation by (suffix) arrays seems possible and could be more space efficient.

Is compression applicable?
